Introduction

Operating System (OS)

Expressions

Debian[1]

Chapter 1

Problem: maintain operating systems

Depending on the different use cases, maintaining operating systems leads to thinking about:

- updates
- unavailability
- backups policy
- testing backups
- snapshots
- restorations
- configuration recipes

1.1 File systems, installed on partitions, with write access

1.1.1 Conventional file systems

- ext2
- ext3
- ext4
- jfs

- xfs

Pros:

- TODO

Cons:

- TODO

1.1.2 File systems managed with configuration recipes

- ansible
- chef
- puppet

Pros:

- TODO

Cons:

- TODO

1.1.3 File systems supporting snapshots

- btrfs
- zfs

Pros:

- TODO

Cons:

- TODO

1.2 Live images, without installation, with read access

1.2.1 Boot without persistent storage

Pros:

- TODO

Cons:

- TODO

1.2.2 Boot with persistent storage

Pros:

- TODO

Cons:

- TODO

1.3 Existing alternatives

1.3.1 Windows Unified Write Filter

Chapter 2

Proposal: an incremental live workflow

Pros:

- reboot = restore
- update = backup
- separation of system and data

Cons:

- exhaustive manual procedure

2.1 Implement the workflow

2.1.1 Mirror official and third-party repositories

Pros:

- TODO

Cons:

- TODO

2.1.1.1 Synchronize local mirrors

apt-mirror

- translations (Translation-*.bz2)
- architecture independant contents (Contents-all.gz)
- Contents-*/InRelease with some third-party repositories

debmirror

ftpsync

2.1.1.2 Select useful architectures

amd64

arm64

armhf

i386

2.1.1.3 Check integrity

Pros:

- avoid errors during future package installations

Cons:

- no tool exists

2.1.2 Build a live file system

Debian GNU/Linux

2.1.2.1 Install specific packages

Bare metal

Virtual machine

Container

2.1.2.2 Create a minimal file system base

debootstrap

2.1.2.3 Turn a system into a systems factory

2.1.2.4 Turn a file system into a live one

live-boot

update-initramfs

2.1.2.5 Install additional packages

2.1.2.6 Link specific data to persistent storage

2.1.3 Encapsulate in an image file

2.1.3.1 Use a format suited for read-only mounting

SquashFS

2.1.3.2 Choose a compression algorithm

gzip

lzma

lzo

lz4

xz

zstd

2.1.3.3 Encapsulate in a hybrid image file

ISO

2.1.4 Secure the produced image file

2.1.4.1 Compute an integrity checksum

SHA-256

SHA-512

2.1.4.2 Sign to certify authenticity

2.1.5 Boot secure image files

2.1.5.1 Create standalone boot images

GRUB

BIOS

UEFI

Secure boot

2.1.5.2 Create a boot menu

grub.cfg

loopback

squash4

iso9660

2.1.5.3 Check integrity and authenticity

gcry_sha256

gcry_sha512

pgp

2.1.5.4 Load images in random access memory

overlayfs

2.1.6 Incremental updating

2.1.6.1 Create a new image file

2.1.6.2 Avoid an unnecessary reboot

Pros:

- no down time
- just replay the modifications on the system in memory

Cons:

- TODO

2.1.6.3 Reduce the duration of a mandatory reboot

kexec-tools

2.2 Automate the workflow

2.2.1 Check integrity of local repositories

2.2.2 Build complete live file systems from scratch

2.2.3 Create new files by updating existing images

2.2.4 Generate a boot menu on-the-fly

Chapter 3

Results

Conclusion

Appendix A
